## INDAZOLE BENZIMIDAZOLE COMPOUNDS AS TYROSINE AND SERINE/THREONINE KINASE INHIBITORS

### FIELD OF THE INVENTION

This invention pertains generally to methods and compositions for treating a variety of patients and cell subjects. More particularly, the present invention provides novel compositions of matter and methods for angiogenesis inhibition, treating cancer, treating diabetes, stimulating insulin-dependent processes, treating Alzheimer's disease, treating central nervous system disorders, prolonging immune responses, reducing the splitting of centrosomes, blocking DNA repair, modulating cell cycle arrest, and inhibiting enzymes such as serine/threonine kinases and tyrosine kinases. The present invention thus has application in the areas of oncology, diabetes, immunology, and medicinal chemistry.

### BACKGROUND OF THE INVENTION

Capillaries reach into almost all tissues of the human body and supply tissues with oxygen and nutrients as well as removing harmful waste products.

Under typical conditions, the endothelial cells lining capillaries do not divide, and capillaries, therefore, do not normally increase in number or size in a human adult. Under certain normal conditions, however, such as when a tissue is damaged, or during certain parts of the menstrual cycle, capillaries begin to proliferate rapidly. This process of forming new capillaries from pre-existing blood vessels is known as angiogenesis or neovascularization. See Folkman, J. Scientific American 275, 150-154 (1996). Angiogenesis during wound healing is an example of pathophysiological neovascularization during adult life. During wound healing, the additional capillaries provide a supply of oxygen and nutrients, promote granulation tissue, and aid in waste removal. After termination of the healing process, the capillaries normally regress. Lymboussaki, A. "Vascular Endothelial Growth Factors and their Receptors in Embryos, Adults, and in Tumors" Academic

-2-

Dissertation, University of Helsinki, Molecular/Cancer Biology Laboratory and Department of Pathology, Haartman Institute, (1999).

Angiogenesis also plays an important role in the growth of cancer cells. It is known that once a nest of cancer cells reaches a certain size, roughly 1  
5 to 2 mm in diameter, the cancer cells must develop a blood supply in order for the tumor to grow larger as diffusion will not be sufficient to supply the cancer cells with enough oxygen and nutrients. A compound that inhibits angiogenesis will thus act to retard or halt the growth of cancer cells.

Receptor tyrosine kinases (RTKs) are polypeptides that regulate  
10 developmental cell growth and differentiation and remodeling and regeneration of adult tissues. Mustonen, T. et al., J. Cell Biology 129, 895-898 (1995); van der Geer, P. et al. Ann Rev. Cell Biol. 10, 251-337 (1994). Polypeptide ligands known as growth factors or cytokines, are known to activate RTKs. Signaling involves ligand binding and a shift in conformation in the external domain of the receptor  
15 resulting in its dimerization. Lymboussaki, A. "Vascular Endothelial Growth Factors and their Receptors in Embryos, Adults, and in Tumors" Academic Dissertation, University of Helsinki, Molecular/Cancer Biology Laboratory and Department of Pathology, Haartman Institute, (1999); Ullrich, A. et al., Cell 61, 203-212 (1990). Binding of the ligand to the RTK results in receptor trans-  
20 phosphorylation at specific tyrosine residues and activation of the catalytic domains for the phosphorylation of cytoplasmic substrates. Id.

Two subfamilies of RTKs are specific to the vascular endothelium. These include the VEGF subfamily and the Tie receptor subfamily. Class III RTKs include VEGFR-1, VEGFR-2, and VEGFR-3. Shibuya, M. et al., Oncogene 5,  
25 519-525 (1990); Terman, B. et al., Oncogene 6, 1677-1683 (1991); Aprelikova, O. et al., Cancer Res. 52, 746-748 (1992).

A number of substances have been identified that promote angiogenesis. These include angiopoietin-1, basic fibroblast growth factor (bFGF)

-3-

and vascular endothelial growth factor (VEGF). VEGF was first described as a protein able to induce vascular permeability and endothelial cell proliferation and was identified as a major inducer of angiogenesis and vasculogenesis. Ferrara, N. et al., *Endocrinol. Rev.* 18, 4-25 (1997). VEGF is known to specifically bind to  
5 RTKs including VEGFR-1 and VEGFR-2. DeVries, C. et al., *Science* 255, 989-991 (1992); Quinn, T. et al., *Proc. Natl. Acad. Sci.* 90, 7533-7537 (1993). It is now known that VEGF stimulates the migration and proliferation of endothelial cells and induces angiogenesis both in vitro and in vivo. Connolly, D. et al., *J. Biol. Chem.* 264, 20017-20024 (1989); Connolly, D. et al., *J. Clin. Invest.* 84, 1470-  
10 1478 (1989); Ferrara, N. et al., *Endocrino. Rew.* 18, 4-25 (1997); Leung, D. et al., *Science* 246, 1306-1309 (1989); Plouet, J. et al., *EMBO J* 8, 3801-3806 (1989).

Because angiogenesis is known to be critical to the growth of cancer and to be controlled by VEGF and VEGF-RTK, substantial efforts have been undertaken to develop compounds which inhibit or retard angiogenesis and inhibit  
15 VEGF-RTK.

Platelet derived growth factor receptor kinase (PDGFRK) is another type of RTK. PDGF expression has been shown in a number of different solid tumors, from glioblastomas to prostate carcinomas. In these various tumor types, the biological role of PDGF signaling can vary from autocrine stimulation of  
20 cancer cell growth to more subtle paracrine interactions involving adjacent stroma and angiogenesis. Therefore, inhibiting the PDGFR kinase activity with small molecules may interfere with tumor growth and angiogenesis.

Tie-2 is a membrane RTK. Upon binding to its ligand, Tie-2 is activated and phosphorylates its downstream signal proteins. Tie-2 kinase activity  
25 may then trigger a pathway of cellular response that leads to stabilization of vascular vessels in cancer. Therefore, blocking kinase activity of Tie-2, in synergy with blockage of activity of other angiogenic kinases such as VEGF and bFGF receptor kinases, may be effective in cutting off the blood supply to cancer cells and in treating the disease.

Glycogen synthase kinase 3 (GSK-3) is a serine/threonine kinase for which two isoforms,  $\alpha$  and  $\beta$ , have been identified. Woodgett, *Trends Biochem. Sci.*, 16:177-81 (1991). Both GSK-3 isoforms are constitutively active in resting cells. GSK-3 was originally identified as a kinase that inhibits glycogen synthase by direct phosphorylation. Upon insulin activation, GSK-3 is inactivated, thereby allowing the activation of glycogen synthase and possibly other insulin-dependent events, such as glucose transport. Subsequently, it has been shown that GSK-3 activity is also inactivated by other growth factors that, like insulin, signal through receptor tyrosine kinases (RTKs). Examples of such signaling molecules include IGF-1 and EGF. Saito et al., *Biochem. J.*, 303:27-31 (1994); Welsh et al., *Biochem. J.* 294:625-29 (1993); and Cross et al., *Biochem. J.*, 303:21-26 (1994).

Agents that inhibit GSK-3 activity are useful in the treatment of disorders that are mediated by GSK-3 activity. In addition, inhibition of GSK-3 mimics the activation of growth factor signaling pathways and consequently GSK-3 inhibitors are useful in the treatment of diseases in which such pathways are insufficiently active. Examples of diseases that can be treated with GSK-3 inhibitors are described below.

Type 2 diabetes is an increasingly prevalent disease of aging. It is initially characterized by decreased sensitivity to insulin and a compensatory elevation in circulating insulin concentrations, the latter of which is required to maintain normal blood glucose levels. Increased insulin levels are caused by increased secretion from the pancreatic beta cells, and the resulting hyperinsulinemia is associated with cardiovascular complications of diabetes. As insulin resistance worsens, the demand on the pancreatic beta cells steadily increases until the pancreas can no longer provide adequate levels of insulin, resulting in elevated levels of glucose in the blood. Ultimately, overt hyperglycemia and hyperlipidemia occur, leading to the devastating long-term complications associated with diabetes, including cardiovascular disease, renal failure and blindness. The exact mechanism(s) causing type 2 diabetes are unknown, but result in impaired

-5-

glucose transport into skeletal muscle and increased hepatic glucose production, in addition to inadequate insulin response. Dietary modifications are often ineffective, therefore the majority of patients ultimately require pharmaceutical intervention in an effort to prevent and/or slow the progression of the complications of the disease.

5 Many patients can be treated with one or more of the many oral anti-diabetic agents available, including sulfonylureas, to increase insulin secretion. Examples of sulfonylurea drugs include metformin for suppression of hepatic glucose production, and troglitazone, an insulin-sensitizing medication. Despite the utility of these agents, 30-40% of diabetics are not adequately controlled using these medications

10 and require subcutaneous insulin injections. Additionally, each of these therapies has associated side effects. For example, sulfonylureas can cause hypoglycemia and troglitazone can cause severe hepatotoxicity. Presently, there is a need for new and improved drugs for the treatment of prediabetic and diabetic patients.

As described above, GSK-3 inhibition stimulates insulin-dependent

15 processes and is consequently useful in the treatment of type 2 diabetes. Recent data obtained using lithium salts provides evidence for this notion. The lithium ion has recently been reported to inhibit GSK-3 activity. Klein et al., *PNAS* 93:8455-9 (1996). Since 1924, lithium has been reported to have antidiabetic effects including the ability to reduce plasma glucose levels, increase glycogen uptake, potentiate

20 insulin, up-regulate glucose synthase activity and to stimulate glycogen synthesis in skin, muscle and fat cells. However, lithium has not been widely accepted for use in the inhibition of GSK-3 activity, possibly because of its documented effects on molecular targets other than GSK-3. The purine analog 5-iodotubercidin, also a GSK-3 inhibitor, likewise stimulates glycogen synthesis and antagonizes inactivation

25 of glycogen synthase by glucagon and vasopressin in rat liver cells. Fluckiger-Isler et al., *Biochem J.* 292:85-91 (1993); and Massillon et al., *Biochem J.* 299:123-8 (1994). However, this compound has also been shown to inhibit other serine/threonine and tyrosine kinases. Massillon et al., *Biochem J.* 299:123-8 (1994).

GSK-3 is also involved in biological pathways relating to Alzheimer's disease (AD). The characteristic pathological features of AD are extracellular plaques of an abnormally processed form of the amyloid precursor protein (APP), so called  $\beta$ -amyloid peptide ( $\beta$ -AP) and the development of intracellular neurofibrillary tangles containing paired helical filaments (PHF) that consist largely of hyperphosphorylated tau protein. GSK-3 is one of a number of kinases that have been found to phosphorylate tau protein in vitro on the abnormal sites characteristic of PHF tau, and is the only kinase also demonstrated to do this in living cells and in animals. Lovestone et al., *Current Biology* 4:1077-86 (1994); and Brownlees et al., *Neuroreport* 8: 3251-3255 (1997). Furthermore, the GSK-3 kinase inhibitor, LiCl, blocks tau hyperphosphorylation in cells. Stambolic et al., *Current Biology* 6:1664-8 (1996). Thus GSK-3 activity may contribute to the generation of neurofibrillary tangles and consequently to disease progression. Recently it has been shown that GSK-3 $\beta$  associates with another key protein in AD pathogenesis, presenillin 1 (PS1). Takashima et al., *PNAS* 95:9637-9641 (1998). Mutations in the PS1 gene lead to increased production of  $\beta$ -AP, but the authors also demonstrate that the mutant PS1 proteins bind more tightly to GSK-3 $\beta$  and potentiate the phosphorylation of tau, which is bound to the same region of PS1.

It has also been shown that another GSK-3 substrate,  $\beta$ -catenin, binds to PS1. Zhong et al., *Nature* 395:698-702 (1998). Cytosolic  $\beta$ -catenin is targeted for degradation upon phosphorylation by GSK-3 and reduced  $\beta$ -catenin activity is associated with increased sensitivity of neuronal cells to  $\beta$ -AP induced neuronal apoptosis. Consequently, increased association of GSK-3 $\beta$  with mutant PS1 may account for the reduced levels of  $\beta$ -catenin that have been observed in the brains of PS1-mutant AD patients and to the disease related increase in neuronal cell-death. Consistent with these observations, it has been shown that injection of GSK-3 antisense but not sense, blocks the pathological effects of  $\beta$ -AP on neurons in vitro, resulting in a 24 hour delay in the onset of cell death and increased cell survival at 1 hr from 12 to 35%. Takashima et al., *PNAS* 90:7789-93. (1993). In these latter studies, the effects on cell-death are preceded (within 3-6 hours of  $\beta$ -AP

-7-

administration) by a doubling of intracellular GSK-3 activity, suggesting that in addition to genetic mechanisms that increase the proximity of GSK-3 to its substrates,  $\beta$ -AP may actually increase GSK-3 activity. Further evidence for a role for GSK-3 in AD is provided by the observation that the protein expression level  
5 (but, in this case, not specific activity) of GSK-3 is increased by 50% in postsynaptosomal supernatants of AD vs. normal brain tissue. Pei et al., *J. Neuropathol Exp.*, 56:70-78 (1997). Thus, specific inhibitors of GSK-3 should slow the progression of Alzheimer's Disease.

In addition to the effects of lithium described above, there is a long  
10 history of the use of lithium to treat bipolar disorder (manic depressive syndrome). This clinical response to lithium may reflect an involvement of GSK-3 activity in the etiology of bipolar disorder, in which case GSK-3 inhibitors could be relevant to that indication. In support of this notion it was recently shown that valproate, another drug commonly used in the treatment of bipolar disorder, is also a GSK-3  
15 inhibitor. Chen et al., *J. Neurochemistry*, 72:1327-1330 (1999). One mechanism by which lithium and other GSK-3 inhibitors may act to treat bipolar disorder is to increase the survival of neurons subjected to aberrantly high levels of excitation induced by the neurotransmitter, glutamate. Nonaka et al., *PNAS* 95: 2642-2647 (1998). Glutamate-induced neuronal excitotoxicity is also believed to be a major  
20 cause of neurodegeneration associated with acute damage, such as in cerebral ischemia, traumatic brain injury and bacterial infection. Furthermore it is believed that excessive glutamate signaling is a factor in the chronic neuronal damage seen in diseases such as Alzheimer's, Huntingdon's, Parkinson's, AIDS associated dementia, amyotrophic lateral sclerosis (AML) and multiple sclerosis (MS).  
25 Thomas, *J. Am. Geriatr. Soc.* 43: 1279-89 (1995). Consequently, GSK-3 inhibitors should provide a useful treatment in these and other neurodegenerative disorders.

GSK-3 phosphorylates transcription factor NF-AT and promotes its export from the nucleus, in opposition to the effect of calcineurin. Beals et al., *Science* 275:1930-33 (1997). Thus, GSK-3 blocks early immune response gene

-8-

activation via NF-AT, and GSK-3 inhibitors may tend to permit or prolong activation of immune responses. Thus, GSK-3 inhibitors are believed to prolong and potentiate the immunostimulatory effects of certain cytokines, and such an effect may enhance the potential of those cytokines for tumor immunotherapy or indeed  
5 for immunotherapy in general.

Lithium has other biological effects. It is a potent stimulator of hematopoiesis, both in vitro and in vivo. Hammond et al., *Blood* 55: 26-28 (1980). In dogs, lithium carbonate eliminated recurrent neutropenia and normalized other blood cell counts. Doukas et al. *Exp. Hematol.* 14: 215-221 (1986). If these effects  
10 of lithium are mediated through the inhibition of GSK-3, GSK-3 inhibitors may have even broader applications. Since inhibitors of GSK-3 are useful in the treatment of many diseases, the identification of new inhibitors of GSK-3 would be highly desirable.

NEK-2 is a mammalian serine threonine kinase, which is structurally  
15 related to the NimA kinase from the fungus *Aspergillus nidulans*. Mutations in NimA result in G2 phase arrest of cells and overexpression of wt NimA results in premature chromatin condensation, even when ectopically expressed in mammalian cells. Both protein and kinase levels peak in S/G2 phase of the cell cycle. NimA also appears to be required for the localization of cdk1/cyclinB complex to the  
20 nucleus and spindle pole body. Histone H3 has been shown to be an in vitro substrate for the kinase, and if this is also the case in vivo, it may explain the role of the kinase in chromosome condensation. Six NimA kinases have been identified to date in mammals, and of these, NEK-2 appears to be the most closely related to NimA. It's activity is also cell cycle regulated, peaking in S/G2 phase.  
25 Overexpression of NEK-2, however, does not affect chromatin condensation but instead results in a pronounced splitting of centrosomes, possibly due to the loss of centriole/centriole adhesion. There is evidence that NEK-2 is regulated by phosphorylation and can interact with protein phosphatase PP1. NEK-2 is ubiquitously expressed and appears to be most abundant in testis. Hyseq cluster

-9-

374113, containing only NEK-2 sequences shows dramatic overexpression of NEK-2 in lymph node metastasis (13.3x) and in primary tumor (6.5x). Inhibition of NEK-2 by antisense oligonucleotides inhibited cell proliferation and reduced the capability of cells to grow in soft agar. In addition, increased cell death was

5 observed in these cells both in the presence and absence of cisplatin.

Ultraviolet light, ionizing radiation, environmental agents and cytotoxic drugs can result in damage to cellular DNA integrity. When such damage occurs during DNA replication or cell division it is potentially catastrophic and may result in cell death. The cellular response is to arrest the cell cycle at one of two

10 checkpoints (G1/S or G2/M) to either permit DNA repair or initiate apoptosis.

The G1/S checkpoint is regulated by the p53 transcriptional activator protein and the absence of this critical protein is often an important step in tumorigenesis, thus defining p53 as a tumor suppressor. In fact, nearly 50% of all

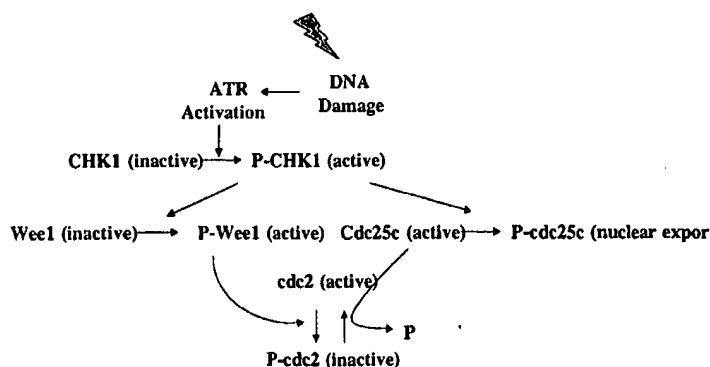

15 cancers are p53 defective due to mutation. T. Soussi, *Ann. N.Y. Acad. Sci.*, 910, 121 (2001). In response to DNA damage, checkpoint kinase 2 (CHK-2) phosphorylates p53 and this results in stabilization of the protein and an elevation in p53 levels. A. Hirao et al., *Science*, 287, 1824 (2000). Consequently, negative cell cycle regulators, such as p21Waf1/Cip1, are activated and halt the cell cycle at the G1/S

20 checkpoint. B. Vogelstein et al., *Nature*, 408, 307 (2000).

The G2/M checkpoint is monitored by the serine/threonine checkpoint kinase 1 (CHK-1). Upon DNA damage, the protein kinase ATR (ataxia-telangiectasia mutated - rad53 related kinase) is activated. H. Zhao et al., *Mol. Cell Biol.*, 21, 4129 (2001); Q. Liu et al., *Genes Dev.*, 14, 1448 (2000). SATR-

-10-

dependent phosphorylation of CHK-1 promotes its phosphorylation of cdc25 and Wee1 and ultimately inactivation of cdc 2. Thus, CHK-1 phosphorylation of cdc25c targets it for nuclear export to the cytoplasm and as a result the cdc25c phosphatase is rendered unavailable to activate cdc 2 by dephosphorylation. Y. Sanchez et al., *Science*, 277, 1497 (1997); C. Y. Peng et al., *Science*, 277, 1501 (1997); T. A. Chen et al., *Nature*, 401, 616 (1999); and A. Lopez-Girona et al., *Nature*, 397, 172 (1999). In addition, CHK-1 activates the protein kinase Wee1, which phosphorylates and inactivates cdc 2. J. Lee et al. *Mol. Biol. Cell*, 12, 551 (2001); L. L. Parker et al., *Science*, 257, 1955 (1992). These dual pathways thus converge to result in cell cycle arrest. Because cell cycle arrest is a potential mechanism by which tumor cells can overcome the damage induced by cytotoxic agents, abrogation of these checkpoints with novel therapeutic agents should increase the sensitivity of tumors to chemotherapy. The presence of two checkpoints, coupled with the tumor specific abrogation of one of these by p53 mutations in 50% of cancers, can be exploited to design tumor-selective agents. Thus, in p53 minus tumors, therapeutic inhibition of G2/M arrest leaves cancerous cells no options for DNA damage repair and results in apoptosis. Normal cells have wild type p53 and retain an intact G1/S checkpoint. Thus these cells have an opportunity to correct DNA damage and survive. One approach to the design of chemosensitizers that abrogate the G2/M checkpoint is to identify inhibitors of the key G2/M regulatory kinase, CHK-1.

-11-

hormone receptors and being useful for stimulating osteoblast proliferation and bone growth. The compounds are also disclosed as being useful in the treatment or prevention of diseases associated with nuclear hormone receptor families.

20 useful as inhibitors of the enzyme poly(ADP-ribose)polymerase and for use in producing medicaments.

25 disorders, prolong immune responses, reduce the splitting of centrosomes, block DNA repair, modulate cell cycle arrest, and/or inhibit enzymes such as flt-1 (VEGFR2), KDR (VEGFR2), Flk-1, bFGFR, GSK-3, NEK-2, CHK-1, Tie-2, PDGF, and cdc 2, and pharmaceutical formulations and medicaments that contain

Generally, reference to a certain element such as hydrogen or H is meant to include all isotopes of that element. For example, if an R group is defined to include hydrogen or H, it also includes deuterium and tritium.

20 The phrase “unsubstituted alkyl” refers to alkyl groups that do not contain heteroatoms. Thus the phrase includes straight chain alkyl groups such as methyl, ethyl, propyl, butyl, pentyl, hexyl, heptyl, octyl, nonyl, decyl, undecyl, dodecyl and the like. The phrase also includes branched chain isomers of straight chain alkyl groups, including but not limited to, the following which are provided

-62-

- by way of example:  $-\text{CH}(\text{CH}_3)_2$ ,  
 $-\text{CH}(\text{CH}_3)(\text{CH}_2\text{CH}_3)$ ,  $-\text{CH}(\text{CH}_2\text{CH}_3)_2$ ,  $-\text{C}(\text{CH}_3)_3$ ,  $-\text{C}(\text{CH}_2\text{CH}_3)_3$ ,  
 $-\text{CH}_2\text{CH}(\text{CH}_3)_2$ ,  $-\text{CH}_2\text{CH}(\text{CH}_3)(\text{CH}_2\text{CH}_3)$ ,  $-\text{CH}_2\text{CH}(\text{CH}_2\text{CH}_3)_2$ ,  $-\text{CH}_2\text{C}(\text{CH}_3)_3$ ,  $-\text{CH}_2\text{C}(\text{CH}_2\text{CH}_3)_3$ ,  
 $-\text{CH}(\text{CH}_3)\text{CH}(\text{CH}_3)(\text{CH}_2\text{CH}_3)$ ,  $-\text{CH}_2\text{CH}_2\text{CH}(\text{CH}_3)_2$ ,  
5  $-\text{CH}_2\text{CH}_2\text{CH}(\text{CH}_3)(\text{CH}_2\text{CH}_3)$ ,  $-\text{CH}_2\text{CH}_2\text{CH}(\text{CH}_2\text{CH}_3)_2$ ,  $-\text{CH}_2\text{CH}_2\text{C}(\text{CH}_3)_3$ ,  
 $-\text{CH}_2\text{CH}_2\text{C}(\text{CH}_2\text{CH}_3)_3$ ,  $-\text{CH}(\text{CH}_3)\text{CH}_2\text{CH}(\text{CH}_3)_2$ ,  
 $-\text{CH}(\text{CH}_3)\text{CH}(\text{CH}_3)\text{CH}(\text{CH}_3)_2$ ,  $-\text{CH}(\text{CH}_2\text{CH}_3)\text{CH}(\text{CH}_3)\text{CH}(\text{CH}_3)(\text{CH}_2\text{CH}_3)$ , and  
others. The phrase also includes cyclic alkyl groups such as cyclopropyl,  
cyclobutyl, cyclopentyl, cyclohexyl, cycloheptyl, and cyclooctyl and such rings  
10 substituted with straight and branched chain alkyl groups as defined above. Thus  
the phrase unsubstituted alkyl groups includes primary alkyl groups, secondary alkyl  
groups, and tertiary alkyl groups. Unsubstituted alkyl groups may be bonded to one  
or more carbon atom(s), oxygen atom(s), and/or nitrogen atom(s) in the parent  
compound. Preferred unsubstituted alkyl groups include straight and branched chain  
15 alkyl groups and cyclic alkyl groups having 1 to 20 carbon atoms. More preferred  
such unsubstituted alkyl groups have from 1 to 10 carbon atoms while even more  
preferred such groups have from 1 to 8, from 1 to 6 or from 1 to 4 carbon atoms.  
Other preferred unsubstituted alkyl groups include straight and branched chain alkyl  
groups having from 1 to 3 carbon atoms and include methyl, ethyl, propyl, and -  
20  $\text{CH}(\text{CH}_3)_2$ .

The phrase "substituted alkyl" refers to an unsubstituted alkyl group  
as defined above in which one or more bonds to a carbon(s) or hydrogen(s) are  
replaced by a bond to non-hydrogen and non-carbon atoms such as, but not limited  
to, a halogen atom such as F, Cl, Br, and I; an oxygen atom in groups such as  
25 hydroxyl groups, alkoxy groups, aryloxy groups, and ester groups; a sulfur atom in  
groups such as thiol groups, alkyl and aryl sulfide groups, sulfone groups, sulfonyl  
groups, and sulfoxide groups; a nitrogen atom in groups such as amines, amides,  
alkylamines, dialkylamines, arylamines, alkylarylamines, diarylamines, N-oxides,  
imides, and enamines; a silicon atom in groups such as in trialkylsilyl groups,  
30 dialkylarylsilyl groups, alkylarylsilyl groups, and triarylsilyl groups; and other

- heteroatoms in various other groups. Substituted alkyl groups also include groups in which one or more bonds to a carbon(s) or hydrogen(s) atom is replaced by a higher-order bond (e.g., a double- or triple-bond) to a heteroatom such as oxygen in oxo, carbonyl, carboxyl, and ester groups; nitrogen in groups such as imines, oximes, hydrazones, and nitriles. Substituted alkyl groups further include alkyl groups in which one or more bonds to a carbon(s) or hydrogen(s) atoms is replaced by a bond to an aryl, heterocyclyl group, or cycloalkyl group. Preferred substituted alkyl groups include, among others, alkyl groups in which one or more bonds to a carbon or hydrogen atom is/are replaced by one or more bonds to fluorine atoms.
- 10 Another preferred substituted alkyl group is the trifluoromethyl group and other alkyl groups that contain the trifluoromethyl group. Other preferred substituted alkyl groups include those in which one or more bonds to a carbon or hydrogen atom is replaced by a bond to an oxygen atom such that the substituted alkyl group contains a hydroxyl, alkoxy, or aryloxy group. Still other preferred substituted
- 15 alkyl groups include alkyl groups that have an amine, or a substituted or unsubstituted alkylamine, dialkylamine, arylamine, (alkyl)(aryl)amine, diarylamine, heterocyclylamine, diheterocyclylamine, (alkyl)(heterocyclyl)amine, or (aryl)(heterocyclyl)amine group.

- The phrase "unsubstituted aryl" refers to aryl groups that do not contain heteroatoms. Thus the phrase includes, but is not limited to, groups such as phenyl, biphenyl, anthracenyl, naphthenyl by way of example. Although the phrase "unsubstituted aryl" includes groups containing condensed rings such as naphthalene, it does not include aryl groups that have other groups such as alkyl or halo groups bonded to one of the ring members as aryl groups such as tolyl are
- 20 substituted aryl groups. A preferred unsubstituted aryl group is phenyl. Unsubstituted aryl groups may be bonded to one or more carbon atom(s), oxygen atom(s), and/or nitrogen atom(s) in the parent compound.

The phrase "substituted aryl group" has the same meaning with respect to unsubstituted aryl groups that substituted alkyl groups had with respect to

-64-

unsubstituted alkyl groups. A substituted aryl group includes aryl groups in which one of the aromatic carbons is bonded to a non-carbon or non-hydrogen atom and also includes aryl groups in which one or more aromatic carbons of the aryl group is bonded to a substituted and/or unsubstituted alkyl group. Thus, the phrase

5 "substituted aryl" includes, but is not limited to tolyl, and hydroxyphenyl among others.

The phrase "unsubstituted arylalkyl" refers to unsubstituted alkyl groups as defined above in which a hydrogen or carbon bond of the unsubstituted alkyl group is replaced with a bond to an aryl group as defined above. For

10 example, methyl ( $-\text{CH}_3$ ) is an unsubstituted alkyl group. If a hydrogen atom of the methyl group is replaced by a bond to a phenyl group, such as if the carbon of the methyl were bonded to a carbon of benzene, then the compound is an unsubstituted arylalkyl group. Thus the phrase includes, but is not limited to, groups such as benzyl, diphenylmethyl,

15  $-\text{CH}(\text{C}_6\text{H}_5)(\text{CH}_3)$ , and  $-\text{CH}_2\text{CH}_2(\text{C}_6\text{H}_5)$  among others.

The phrase "substituted arylalkyl" has the same meaning with respect to unsubstituted arylalkyl groups that substituted aryl groups had with respect to unsubstituted aryl groups. However, a substituted arylalkyl group also includes groups in which a carbon or hydrogen bond of the alkyl part of the group is

20 replaced by a bond to a non-carbon or a non-hydrogen atom. Examples of substituted arylalkyl groups include, but are not limited to,  $-\text{CH}_2\text{C}(=\text{O})(\text{C}_6\text{H}_5)$ , and  $-\text{CH}_2(2\text{-methylphenyl})$  among others.

The phrase "unsubstituted heterocyclyl" refers to both aromatic and nonaromatic ring compounds containing 3 or more ring members of which one or

25 more is a heteroatom such as, but not limited to, N, O, and S. Although the phrase "unsubstituted heterocyclyl" includes condensed heterocyclic rings such as benzimidazolyl and indazolyl, it does not include heterocyclyl groups that have other groups such as alkyl or halo groups bonded to one of the ring members because compounds such as 2-methylbenzimidazolyl are substituted heterocyclyl groups.

-66-

membered rings containing an oxygen atom and 1 to 2 sulfur atoms such as, but not limited to, dihydrooxathiinyl; saturated 3 to 8 membered rings containing 1 to 2 oxygen atoms and 1 to 2 sulfur atoms such as 1,4-oxathiane; unsaturated condensed rings containing 1 to 2 sulfur atoms such as benzothienyl, benzodithiinyl; and

5 unsaturated condensed heterocyclic rings containing an oxygen atom and 1 to 2 oxygen atoms such as benzoxathiinyl. Heterocyclyl group also include those described above in which one or more S atoms in the ring is double bonded to one or two oxygen atoms (sulfoxides and sulfones). For example, heterocyclyl groups include tetrahydrothiophene, tetrahydrothiophene oxide, and tetrahydrothiophene

10 1,1-dioxide. Preferred heterocyclyl groups contain 5 or 6 ring members. More preferred heterocyclyl groups include morpholine, piperazine, piperidine, pyrrolidine, pyridine, 2,5-diazabicyclo[2.2.1]heptane, 1,4-diazacycloheptane, imidazole, pyrazole, 1,2,3-triazole, 1,2,4-triazole, tetrazole, thiomorpholine, pyrrole, homopiperazine, oxazolidin-2-one, pyrrolidin-2-one, oxazole, thiazole,

For example, piperazine is a heterocyclyl group. If a nitrogen or carbon atom of the piperazinyl group is bonded to an unsubstituted aryl group, then the compound is an unsubstituted arylheterocyclyl group if the heterocyclyl group is also unsubstituted save for its point of attachment to the parent compound.

If a hydrogen atom of the methyl group is replaced by a bond to an unsubstituted heterocyclyl group, such as if the carbon of the methyl were bonded to carbon 2 of pyridine (one of the carbons bonded to the N of the pyridine) or carbons 3 or 4 of the pyridine, then the compound is an

The indazole benzimidazoles of the present invention may generally be assembled by coupling a suitably substituted indazole fragment with a suitably substituted 2-amino aniline or 2-nitro aniline compound. In one method, shown in

5 Scheme 1, an indazole-3-carboxylic acid is reacted with  $\text{POCl}_3$  to form a dimer. The resulting dione is then heated in the presence of a suitably substituted diamine to form the desired indazole benzimidazole adduct. If a nitro aniline is used in place of the diamine, an additional reduction and cyclodehydration step is required to effect the ring closure. Alternatively a diamine having one protected amine group

10 may be reacted in place of the diamine. Formation of the indazole benzimidazole by this procedure will include a deprotection and cyclodehydration to afford the desired indazole benzimidazole compound. These reactions may be conducted in aromatic solvents such as toluene and non-nucleophilic bases such as trialkylamines such as triethylamine may be employed.

In some cases, the amide comprising the protected amine group formed by reaction of the first (protected amino)(amino)benzene derivative with the dimer is removed and the product is cyclodehydrated, in one procedure, using an acid. Most commonly used protective groups for amines are stable to the reaction with the dimer. Boc may come off during the reaction with the dimer, but only if the temperature is maintained at from 130-150°C or higher. Examples of protective groups for the amines that are stable upon reaction with the dimer include, but are not limited to, carbamates such as, but not limited to, methyl ethyl, t-butyl, benzyl, and 9-fluorenylmethyl carbamates and the like; amides such as, but not limited to, acetamide, chloroacetamide, trifluoroacetamide, benzamide and the like; sulfonamides such as, but not limited to, benzenesulfonamide, p-toluenesulfonamide, trifluoromethanesulfonamide, and the like; and groups such as, but not limited to, N-allyl, N-benzyl, N-o-nitrobenzyl, N-p-methoxybenzyl, N-2,4-dimethoxybenzyl, N-triphenylmethyl, SEM, and the like.

Groups which are sensitive to acids such as, but not limited to, N-2,4-dimethoxybenzyl, N-triphenylmethyl, may come off during cyclodehydration when it is performed in refluxing AcOH. If the cyclodehydration is performed in the presence of a non nucleophilic base such as triethylamine, some carbamates such as, but not limited to, 9-fluorenylmethyl carbamate and 2,4-dichlorobenzyl carbamate may be cleaved.

The indazole fragment may also be constructed from suitably  
 substituted indoles *via* a nitrosation reaction to form a suitably substituted indazole-  
 15 3-carbaldehyde as the key coupling precursor (Scheme 2). This strategy affords  
 considerable flexibility in the synthesis of functionalized indazole benzimidazoles.  
 By using appropriately substituted indole, 1,2-diaminobenzene, or 1,2-  
 diaminoheteroaryl starting materials, many of which are commercially available or

-219-

- may be easily made by one of skill in the art, a wide variety of desired indazole benzimidazole compounds may be synthesized. Without being bound to hypothesis, it is believed that a hemiaminal intermediate compound is initially obtained which is then cyclooxidized to provide the substituted and unsubstituted indazole benzimidazole compounds of the invention. The suitably substituted indazole-3-carbaldehyde may alternatively be reacted with a suitably substituted monoprotected substituted or unsubstituted 1,2-diaminobenzene to form an imine that includes the protecting group. The intermediate imine product may then be deprotected and oxidatively cyclized to produce the desired indazole benzimidazole product. The suitably substituted indazole-3-carbaldehyde may also be reacted with a suitably substituted benzene bearing at least two amine groups one of which is protected with a suitable protecting group that provides a protected benzimidazole indazole product. Removal of the protecting group in such embodiments affords the indazole benzimidazole product. In another embodiment, the indazole-3-carbaldehyde may be reacted with a monoprotected substituted or unsubstituted 1,2-diaminobenzene derivative in a reaction in which the protecting group is lost and the indazole benzimidazole is formed. Generally, the  $O_2$  for the oxidative cyclization step comes from that dissolved in the solvent in the reaction vessel. In one alternative embodiment,  $O_2$  may be bubbled through the reaction mixture. In other embodiments, compounds which provide a source for  $O_2$  such as nitrobenzene may be used in the oxidative cyclization to form the indazole benzimidazole product.

XVI

5 reacted with the indazole-3-carbaldehyde, the diaminobenzene derivative is a  
compound having the formula XIV as set forth above where  $R^5$ ,  $R^6$ ,  $R^7$ , and  $R^8$  have  
any of the values set forth above with respect to the first, second, third, fourth,

carbaldehyde. In addition, certain  $R^1$ - $R^4$  groups such as  $-OH$  may require  
protection during reaction of the substituted indole with  $NaNO_2/HCl$  and during

In some embodiments of the first alternative method of forming a  
substituted or unsubstituted indazole benzimidazole, the indazole-3-carbaldehyde,  
such as compounds of formula XVI, are formed by reacting a suitably substituted  
20 indole with  $NaNO_2$ . In such procedures, the reaction is generally conducted in the  
dark. The reaction may be protected from light by, for example, covering the  
reaction vessel with an opaque material such as aluminum foil or the like. In such  
procedures, a substituted or unsubstituted indole is generally added to a reaction  
vessel that includes an aqueous solution of  $NaNO_2$  at an acidic pH such as at a pH

-224-

ranging from at or about 2 to a pH of at or about 3. In one embodiment, the pH is at or about 2.5. The  $\text{NaNO}_2$  solution is generally made acidic by adding an acid such as HCl or HBr although other acids may be employed for this purpose. An organic solvent such as dioxane or tetrahydrofuran may be added to the aqueous

5  $\text{NaNO}_2$  solution along with the indole or prior to adding the indole. Generally, the indole is added slowly to the reaction vessel that contains the  $\text{NaNO}_2$  solution.

-225-

Scheme 3 illustrates just a few of the methods that may be used to produce a variety of 1,2-diamino benzenes. Halo (X = halogen) nitroanilines may be reacted with a wide variety of nucleophiles (Nu<sup>-</sup>) such as alcohols and amines to produce functionalized nitroanilines which may subsequently be reduced to diamines. The alcohol moiety of a nitroamino phenol may be modified using known methods to introduce a broad range of substituents into a diamine for subsequent inclusion in an indazole benzimidazole compound.

In addition to the above schemes, it should be noted that various groups, including, but not limited to, hydroxyl groups and amine groups may be

-226-

### Purification and Characterization of Compounds

25                   Compounds of the present invention were characterized by high performance liquid chromatography (HPLC) using a Waters Millenium chromatography system with a 2690 Separation Module (Milford, Massachusetts). The analytical columns were Alltima C-18 reversed phase, 4.6 x 250 mm from Alltech (Deerfield, Illinois). A gradient elution was used, typically starting with 5% acetonitrile/95% water and progressing to 100% acetonitrile over a period of 40 minutes. All solvents contained 0.1% trifluoroacetic acid (TFA). Compounds were

30

-238-

detected by ultraviolet light (UV) absorption at either 220 or 254 nm. HPLC solvents were from Burdick and Jackson (Muskegan, Michigan), or Fisher Scientific (Pittsburg, Pennsylvania). In some instances, purity was assessed by thin layer chromatography (TLC) using glass or plastic backed silica gel plates, such as, for example, Baker-Flex Silica Gel 1B2-F flexible sheets. TLC results were readily detected visually under ultraviolet light, or by employing well known iodine vapor and other various staining techniques.

Mass spectrometric analysis was performed on one of two LCMS instruments: a Waters System (Alliance HT HPLC and a Micromass ZQ mass spectrometer; Column: Eclipse XDB-C18, 2.1 x 50 mm; Solvent system: 5-95% acetonitrile in water with 0.05% TFA; Flow rate 0.8 mL/min; Molecular weight range 150-850; Cone Voltage 20 V; Column temperature 40°C) or a Hewlett Packard System (Series 1100 HPLC; Column: Eclipse XDB-C18, 2.1 x 50 mm; Solvent system: 1-95% acetonitrile in water with 0.05% TFA; Flow rate 0.4 mL/min; Molecular weight range 150-850; Cone Voltage 50 V; Column temperature 30°C). All masses are reported as those of the protonated parent ions.

GCMS analysis was performed on a Hewlett Packard instrument (HP6890 Series gas chromatograph with a Mass Selective Detector 5973; Injector volume: 1 µL; Initial column temperature: 50°C; Final column temperature: 250°C; Ramp time: 20 minutes; Gas flow rate: 1 mL/min; Column: 5% Phenyl Methyl Siloxane, Model #HP 190915-443, Dimensions: 30.0 m x 25 µm x 0.25 µm).

Preparative separations were carried out using either a Flash 40 chromatography system and KP-Sil, 60A (Biotage, Charlottesville, Virginia), or by HPLC using a C-18 reversed phase column. Typical solvents employed for the Flash 40 Biotage system were dichloromethane, methanol, ethyl acetate, hexane and triethyl amine. Typical solvents employed for the reverse phase HPLC were varying concentrations of acetonitrile and water with 0.1% trifluoroacetic acid.

Various functionalized aryl diamines were obtained from commercial sources, prepared by methods known to those of skill in the art, or were prepared by the following general methods:

**METHOD 1**

2,4-Difluoronitrobenzene (1.0 equivalent) was placed in a dry round-bottomed flask equipped with a dry ice condenser charged with acetone and dry ice. Ammonia was condensed into the flask and the resulting solution was stirred at reflux for 7 hours. A yellow precipitate formed within 1 hour. After 7 hours, the condenser was removed and the liquid ammonia was allowed to evaporate over several hours. The crude product was purified by flash chromatography on silica gel (85:15 hexanes:ethyl acetate, product at  $R_f = 0.32$ , contaminant at  $R_f = 0.51$ ); GC/MS ( $m/z$ ) 156.1 ( $M^+$ ),  $R_t$  11.16 minutes.

The resulting 5-fluoro-2-nitrophenylamine (1.0 equivalent) and an amine (1.1 equivalents) e.g. N-methyl piperazine, were dissolved in N-methylpyrrolidinone and triethylamine (2.0 equivalents) was added. The reaction mixture was heated at 100°C for 3 hours. The solution was then cooled to room temperature and diluted with water. The resulting precipitate was filtered and dried under vacuum to provide the 2-amino-4-dialkylamino nitrobenzene or 4-dialkylamino nitroaniline. Alternatively, the same product may be obtained by the reaction of commercially available 5-chloro-2-nitrophenylamine (1.0 equivalent) and an amine (5 equivalents; neat). The two are heated at 130°C for 1-2 days and the product is isolated in an identical manner. LC/MS ( $m/z$ ) 237.1 ( $MH^+$ ),  $R_t$  1.304 minutes.

-240-

The nitroamine (1.0 equivalent) and 10% Pd/C (0.1 equivalents) were suspended in anhydrous ethanol at room temperature. The reaction flask was evacuated and subsequently filled with H<sub>2</sub>. The resulting mixture was then stirred under a hydrogen atmosphere overnight. The resulting solution was filtered  
5 through Celite and concentrated under vacuum to provide the crude product which was used without further purification.

## METHOD 2

A round bottom flask was charged with 2,3-difluoro-6-nitrophenylamine (1 equivalent) and enough NMP to make a viscous slurry. An amine (5 equivalents), e.g. N-methyl piperazine, was added and the solution was heated at 100°C. After 2 hours, the solution was cooled and poured into water. A bright yellow solid formed which was filtered and dried. The nitroamine was reduced as in Method 1 to provide the crude product which was used without further  
15 purification. LC/MS (m/z) 225.1 (MH<sup>+</sup>), R<sub>t</sub> 0.335 minutes.

## METHOD 3

To a 0.1 M DMF solution of 1,3-difluoro-2-nitrobenzene was added Et<sub>3</sub>N (2 equivalents) followed by an amine (1 equivalent), e.g. morpholine. The mixture was stirred for 18 hours and then diluted with water and extracted with ethyl acetate. The combined organic layers were dried over MgSO<sub>4</sub>, filtered, and  
20

-241-

concentrated. LC/MS (m/z): 227.2 (MH<sup>+</sup>), R<sub>t</sub> 2.522 minutes. Ammonia was condensed into a bomb containing the crude product. The bomb was sealed and heated to 100°C (over 400 psi). After 72 hours the bomb was allowed to cool and the ammonia was evaporated to provide a reddish solid. The nitroamine was reduced as in Method 1 to provide the crude product which was used without further purification. LC/MS (m/z) 194.1 (MH<sup>+</sup>), R<sub>t</sub> 1.199 minutes.

**METHOD 4**

To a stirred N-methylpyrrolidinone solution containing NaH (1.3 equivalents) was added an alcohol (1.0 equivalent), e.g. 2-methoxyethanol. The resulting mixture was then stirred for 30 minutes. A slurry of 5-fluoro-2-nitrophenylamine in N-methylpyrrolidinone was then added slowly. The mixture was then heated to 100°C. After 2 hours, the reaction mixture was cooled and water was added. The mixture was then filtered and the solid was washed with water and purified by silica gel chromatography (1:1 ethyl acetate:hexane). LC/MS (m/z) 213.2 (MH<sup>+</sup>), R<sub>t</sub> 2.24 minutes. The nitroamine was reduced as in Method 1 to provide the crude product which was used without further purification. LC/MS (m/z) 183.1 (MH<sup>+</sup>), R<sub>t</sub> 0.984 minutes.

**METHOD 5**

Diisopropyl azodicarboxylate (1.1 equivalents) was added dropwise to a stirred solution of 4-amino-3-nitrophenol (1.0 equivalent), triphenylphosphine

-242-

(1.1 equivalents), and an alcohol, e.g. N-(2-hydroxyethyl)morpholine (1.0 equivalent), in tetrahydrofuran at 0°C. The mixture was allowed to warm to room temperature and stirred for 18 hours. The solvent was evaporated, and the product was purified by silica gel chromatography (98:2 CH<sub>2</sub>Cl<sub>2</sub>:methanol) to yield 4-(2-morpholin-4-ylethoxy)-2-nitrophenylamine as a dark reddish-brown oil. LC/MS (m/z) 268.0 (MH<sup>+</sup>), R<sub>t</sub> 1.01 minutes. The nitroamine was reduced as in Method 1 to give the crude product which was used without further purification. LC/MS (m/z) 238.3 (MH<sup>+</sup>), R<sub>t</sub> 0.295 minutes.

**METHOD 6**

To a flask charged with 4-amino-3-nitrophenol (1 equivalent), K<sub>2</sub>CO<sub>3</sub> (2 equivalents), and 2-butanone was added an alkyl dibromide, e.g. 1,3-dibromopropane (1.5 equivalents). The resulting mixture was then heated at 80°C for 18 hours. After cooling, the mixture was filtered, concentrated, and diluted with water. The solution was then extracted with CH<sub>2</sub>Cl<sub>2</sub> (3 x) and the combined organic layers were concentrated to give a solid that was then washed with pentane. LC/MS (m/z) 275.1 (MH<sup>+</sup>), R<sub>t</sub> 2.74 minutes.

An acetonitrile solution of the bromide prepared above, an amine, e.g. pyrrolidine (5 equivalents), Cs<sub>2</sub>CO<sub>3</sub> (2 equivalents) and Bu<sub>4</sub>NI (0.1 equivalents) was heated at 70°C for 48 hours. The reaction mixture was cooled, filtered, and concentrated. The residue was dissolved in CH<sub>2</sub>Cl<sub>2</sub>, washed with water, and concentrated to give the desired nitroamine, e.g. 2-nitro-4-(3-pyrrolidin-1-ylpropoxy)phenylamine. LC/MS (m/z) 266.2 (MH<sup>+</sup>), R<sub>t</sub> 1.51 minutes. The nitroamine was reduced as in Method 1 to provide the crude product which was used without further purification.

-243-

**METHOD 7**

To a suspension of 6-chloro-3-nitropyridin-2-amine (1 equivalent) in acetonitrile was added an amine, e.g. morpholine (4 equivalents). The resulting  
 5 reaction mixture was stirred at 70°C for 5 hours. The solvent was evaporated under reduced pressure, and the residue triturated with ether to provide the desired compound as a bright yellow powder. LC/MS (m/z) 225.0 (MH<sup>+</sup>), R<sub>t</sub> 1.79 minutes. The nitroamine was reduced as in Method 1 to provide the crude product which was used without further purification.

**EXAMPLE 984****3-[6-((3S)-3,4-Dimethylpiperazinyl)benzimidazol-2-yl]-6-fluoro-1H-indazole****Synthesis of (3S)-3-Methylpiperazine-1-carboxylic acid tert-butyl ester**

To a stirred solution of (2S)-2-methylpiperazine (2 equivalents) in dichloromethane at  $-10^{\circ}\text{C}$ , di-tert-butyl dicarbonate (1 equivalent) was added. The mixture was stirred at  $-10^{\circ}\text{C}$  for two minutes, and subsequently quenched with saturated aqueous  $\text{NaHCO}_3$ . The two phases were separated, and the organic layer

-324-

was extracted with methylene chloride. The organic extracts were collected, dried over  $\text{Na}_2\text{SO}_4$ , and concentrated to give the desired product. LC/MS ( $m/z$ ) 201.0 ( $\text{MH}^+$ ),  $R_t$  1.67 minutes.

#### Synthesis of (2S)-1,2-Dimethyl-piperazine

(3S)-3-Methylpiperazine-1-carboxylic acid tert-butyl ester (1 equivalent) and paraformaldehyde (5 equivalents) were dissolved in a mixture of MeOH and AcOH (5:1) on molecular sieves.  $\text{NaCNBH}_3$  (4 equivalents) was added to the suspension at  $25^\circ\text{C}$ . The slurry was subsequently heated to  $80^\circ\text{C}$ . After 10 hours, the mixture was cooled, filtered, and concentrated. The residue was dissolved in dichloromethane and washed with saturated aqueous  $\text{NaHCO}_3$ . The organic solution was dried ( $\text{Na}_2\text{SO}_4$ ), and concentrated. The tert-butoxycarbonyl group was removed by treating the crude amine with saturated HCl in MeOH at room temperature for 30 minutes. The mixture was then concentrated and excess HCl was removed in-vacuo. The desired (2S)-1,2-dimethylpiperazine was thus obtained as the bis HCl salt. LC/MS ( $m/z$ ) 115.0 ( $\text{MH}^+$ ),  $R_t$  0.33 minutes.

#### Synthesis of 5-(3S)-(3,4-Dimethyl-piperazin-1-yl)-2-nitro-phenylamine

The title compound was prepared from (2S)-1,2-dimethylpiperazine using the procedure described in Method 8 Step 5. LC/MS ( $m/z$ ) 251.3 ( $\text{MH}^+$ ),  $R_t$  1.48 minutes.

Various indazole benzimidazoles are synthesized following the procedure of Example 4 using the nitroanilines of Examples 1024-1033 in combination with a indazole-3-carbaldehyde of formula XVI where  $R^1$ ,  $R^2$ ,  $R^3$ , and  $R^4$  have any of the values described above. For example, various indazole benzimidazoles are synthesized by reacting the nitroanilines of Examples 1024-1033 with 5-fluoroindazole, 5-chloroindazole, 6-fluoroindazole, 6-chloroindazole, 5-methoxyindazole, 6-methoxyindazole, 5-ethoxyindazole, and 6-ethoxyindazole 3-carbaldehydes.

Indazole benzimidazole compounds prepared from the nitroanilines of Examples 1024-1029 are reacted with an acyl halide such as acetyl chloride to provide benzimidazole indazoles with an amide group. In an acetylation procedure, a DMA solution of an indazole benzimidazole (1 equivalent) prepared from a nitroaniline of Examples 1024-1029 is added to a room temperature solution of acetyl chloride (1.5 equivalents) in THF over 15 minutes. After this time,

-340-

triethylamine (4 equivalents) is added dropwise and the reaction mixture is stirred for 2 hours at room temperature. The reaction is then partitioned between EtOAc and water. Aqueous layers are extracted with EtOAc (2x) and the combined extractions are washed with water once. Drying over anhydrous  $\text{MgSO}_4$  and concentration provides an oil that is purified by reverse phase HPLC to provide the desired product.

Indazole benzimidazole compounds prepared from the nitroanilines of Examples 1024-1029 are reacted with an acyl halide such as bromoacetyl chloride to provide benzimidazole indazoles with an amide group that includes a bromide for further reaction. In such an acetylation procedure, a DMA solution of an indazole benzimidazole (1 equivalent) prepared from a nitroaniline of Examples 1024-1029 is added to a room temperature solution of bromoacetyl chloride (1.5 equivalents) in THF over 15 minutes. After this time, triethylamine (4 equivalents) is added dropwise and the reaction mixture is stirred for 2 hours at room temperature. The reaction is then partitioned between EtOAc and water. Aqueous layers are extracted with EtOAc (2x) and the combined extractions are washed with water once. Drying over anhydrous  $\text{MgSO}_4$  and concentration provides an oil that is purified by reverse phase HPLC to provide the desired product.

An indazole benzimidazole compound that has been reacted with a bromoacetyl chloride such as described in the preceding paragraph is further functionalized by reaction with an amine. In such a reaction, the bromoacetylated product resulting from the reaction of the bromoacetyl chloride with an indazole benzimidazole prepared from the nitroanilines of Examples 1024-1029 is suspended in a desired amine such as, but not limited to, N-methylpiperazine, morpholine, and piperidine and the reaction is heated at reflux for 1 hour. The reaction is concentrated and the residue is purified via reverse phase HPLC to provide the desired product in which the bromide has been displaced by the amine.

### ASSAY PROCEDURES

#### In vitro kinase assays for receptor tyrosine kinases

- The kinase activity of various protein tyrosine kinases can be measured by providing ATP and a suitable peptide or protein tyrosine-containing substrate, and assaying the transfer of phosphate moiety to the tyrosine residue. Recombinant proteins corresponding to the cytoplasmic domains of the flt-1 (VEGFR1), Flk-1, Tie-2, PDGF, and bFGF receptors were expressed in Sf9 insect cells using a Baculovirus expression system (InVitrogen) and purified via Glu antibody interaction (for Glu-epitope tagged constructs) or by Metal Ion Chromatography (for His<sub>6</sub> tagged constructs). For each assay, test compounds were serially diluted in DMSO then mixed with an appropriate kinase reaction buffer plus ATP. Kinase protein and an appropriate biotinylated peptide substrate were added to give a final volume of 50-100  $\mu$ L, reactions were incubated for 1-3 hours at room temperature and stopped by the addition of 25-50  $\mu$ L of 45mM EDTA, 50mM Hepes pH 7.5. Stopped reaction mix (75  $\mu$ L) was transferred to a streptavidin coated microtiter plate (Boehringer Mannheim) and incubated for 1 hour.

-365-

Phosphorylated peptide product was measured with the DELFIA time-resolved fluorescence system (Wallac or PE Biosciences), using a Eu-labeled anti-phosphotyrosine antibody PT66 with the modification that the DELFIA assay buffer was supplemented with 1 mM MgCl<sub>2</sub> for the antibody dilution. Time resolved  
5 fluorescence was read on a Wallac 1232 DELFIA fluorometer or a PE Victor II multiple signal reader. The concentration of each compound for 50% inhibition (IC<sub>50</sub>) was calculated by non-linear regression using XL Fit data analysis software.

Flt-1, Flk-1, Tie-2, and bFGFR kinases were assayed in 50 mM Hepes pH 7.0, 2 mM MgCl<sub>2</sub>, 10 mM MnCl<sub>2</sub>, 1 mM NaF, 1 mM DTT, 1 mg/ml  
10 BSA, 2 μM ATP, and 0.20-0.50 μM corresponding biotinylated peptide substrate. Flt-1, Flk-1, Tie-2, and bFGFR kinases were added at 0.1 μg/mL, 0.05 μg/mL, or 0.1 μg/mL respectively. For the PDGFR kinase assay, 120 μg/mL enzyme with the same buffer conditions as above was used except for changing ATP and peptide  
15 substrate concentrations to 1.4 μM ATP, and 0.25 μM biotin-GGLFDDPSYVNVQNL-NH<sub>2</sub> peptide substrate.

#### **In vitro kinase assays for serine/threonine kinases**

The kinase activity of various protein serine/threonine kinases can be measured by providing ATP and a suitable peptide or protein serine/threonine containing substrate, and assaying the transfer of phosphate moiety to the serine or  
20 threonine residue. Recombinant proteins containing the kinase domains of GSK-3, NEK-2, and CHK 1 enzymes were expressed in Sf9 insect cells using a Baculovirus expression system (InVitrogen) and purified via Glu antibody interaction (for Glu-epitope tagged constructs) or by Metal Ion Chromatography (for His<sub>6</sub> tagged constructs). The purified cdc 2 enzyme used in the assay is commercially available  
25 and was purchased from New England Bio Labs. For each assay, test compounds were serially diluted in DMSO then mixed with an appropriate kinase reaction buffer plus <sup>32</sup>P g-labeled ATP. Kinase protein and an appropriate biotinylated peptide substrate were added to give a final volume of 100 μL. Reactions were incubated for 1-2 hours at room temperature and stopped by the addition of 50 μL

-366-

of a solution of 45 mM EDTA, 50 mM Hepes pH 7.5, 50  $\mu$ L unlabelled ATP. Stopped reaction mix (75  $\mu$ L) was transferred to a streptavidin coated microtiter plate (Boehringer Mannheim) and incubated for 1 hour. Streptavidin plates were washed with PBS, diluted with 200  $\mu$ L Microscint 20 scintillation fluid, sealed, and counted using TopCount. The concentration of each compound for 50% inhibition ( $IC_{50}$ ) was calculated by non-linear regression using XL Fit data analysis software.

Each of the compounds produced in Examples 1-728 was synthesized and assayed using the procedures described above. The majority of the exemplary compounds displayed an  $IC_{50}$  value of less than 10  $\mu$ M with respect to VEGFR1, Flk-1, bFGF, Tie-2, CHK-1, cdc2, GSK-3, NEK-2, and PDGF. In addition, many of the exemplary compounds exhibited  $IC_{50}$  values in the nM range and showed potent activity with respect to VEGFR1, Flk-1, bFGF, Tie-2, CHK-1, cdc2, GSK-3, NEK-2, and PDGF with  $IC_{50}$  values of less than 1  $\mu$ M. The other examples also exhibited such activity with respect to VEGFR1, Flk-1, bFGF, Tie-2, CHK-1, cdc2, GSK-3, NEK-2, and PDGF or will be shown to exhibit such activity. The exemplary compounds also exhibit inhibition activity with respect to KDR.
